What is a Thread?
Threads

- Why threads?
  - Need to handle concurrent processes

- Definition
  - Single sequential flow of control within a program
  - For simplicity, think of threads as processes executed by a program
  - Example:
    - Operating System
    - HotJava web browser
Threads
Multi-threading in Java Platform

• Every application has at least one thread — or several, if you count "system" threads that do things like memory management and signal handling

• But from the application programmer's point of view, you start with just one thread, called the main thread. This thread has the ability to create additional threads
Thread States
Thread States

• A thread can be in one of several possible states:
  1. Running
     • Currently running
     • In control of CPU
  2. Ready to run
     • Can run but not yet given the chance
  3. Resumed
     • Ready to run after being suspended or blocked
  4. Suspended
     • Voluntarily allowed other threads to run
  5. Blocked
     • Waiting for some resource or event to occur
Thread Priorities
Thread Priorities

- Why priorities?
  - Determine which thread receives CPU control and gets to be executed first

- Definition:
  - Integer value ranging from 1 to 10
  - Higher the thread priority $\rightarrow$ larger chance of being executed first

- Example:
  - Two threads are ready to run
  - First thread: priority of 5, already running
  - Second thread = priority of 10, comes in while first thread is running
Thread Priorities

• Context switch
  – Occurs when a thread snatches the control of CPU from another
  – When does it occur?
    • Running thread voluntarily relinquishes CPU control
    • Running thread is preempted by a higher priority thread
• More than one highest priority thread that is ready to run
  – Deciding which receives CPU control depends on the operating system
  – Windows 95/98/NT: Uses time-sliced round-robin
  – Solaris: Executing thread should voluntarily relinquish CPU control
Thread Class
The *Thread* Class: Constructor

- Has eight constructors

<table>
<thead>
<tr>
<th>Thread Constructors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thread()</td>
</tr>
<tr>
<td>Creates a new <em>Thread</em> object.</td>
</tr>
<tr>
<td>Thread(String name)</td>
</tr>
<tr>
<td>Creates a new <em>Thread</em> object with the specified <em>name</em>.</td>
</tr>
<tr>
<td>Thread(Runnable target)</td>
</tr>
<tr>
<td>Creates a new <em>Thread</em> object based on a <em>Runnable</em> object. <em>target</em> refers to the object whose run method is called.</td>
</tr>
<tr>
<td>Thread(Runnable target, String name)</td>
</tr>
<tr>
<td>Creates a new <em>Thread</em> object with the specified name and based on a <em>Runnable</em> object.</td>
</tr>
</tbody>
</table>
## The *Thread* Class: Constants

- Contains fields for priority values

<table>
<thead>
<tr>
<th>Thread Constants</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>public final static int MAX_PRIORITY</td>
<td>The maximum priority value, 10.</td>
</tr>
<tr>
<td>public final static int MIN_PRIORITY</td>
<td>The minimum priority value, 1.</td>
</tr>
<tr>
<td>public final static int NORM_PRIORITY</td>
<td>The default priority value, 5.</td>
</tr>
</tbody>
</table>
The *Thread* Class: Methods

- Some *Thread* methods

<table>
<thead>
<tr>
<th>Thread Methods</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>public static Thread currentThread()</td>
<td>Returns a reference to the thread that is currently running.</td>
</tr>
<tr>
<td>public final String getName()</td>
<td>Returns the name of this thread.</td>
</tr>
<tr>
<td>public final void setName(String name)</td>
<td>Renames the thread to the specified argument <code>name</code>. May throw <code>SecurityException</code>.</td>
</tr>
<tr>
<td>public final int getPriority()</td>
<td>Returns the priority assigned to this thread.</td>
</tr>
<tr>
<td>public final boolean isAlive()</td>
<td>Indicates whether this thread is running or not.</td>
</tr>
</tbody>
</table>
Two Ways of Creating Java Threads
Two Ways of Creating and Starting a Thread

1. Extending the *Thread* class
2. Implementing the *Runnable* interface
Extending Thread Class
Extending Thread Class

- The subclass extends `Thread` class
  - The subclass overrides the `run()` method of `Thread` class
- An object instance of the subclass can then be created
- Calling the `start()` method of the object instance starts the execution of the thread
  - Java runtime starts the execution of the thread by calling `run()` method of object instance
Two Schemes of starting a thread from a subclass

1. The `start()` method is not in the constructor of the subclass
   - The `start()` method needs to be explicitly invoked after object instance of the subclass is created in order to start the thread

2. The `start()` method is in the constructor of the subclass
   - Creating an object instance of the subclass will start the thread
Scheme 1: start() method is Not in the constructor of subclass

```java
class PrintNameThread extends Thread {
    
    PrintNameThread(String name) {
        super(name);
    }

    public void run() {
        String name = getName();
        for (int i = 0; i < 100; i++) {
            System.out.print(name);
        }
    }

} //continued
```
Scheme 1: start() method needs to be called explicitly

class ExtendThreadClassTest1 {
    public static void main(String args[]) {
        PrintNameThread pnt1 =
            new PrintNameThread("A");
        pnt1.start(); // Start the first thread
        PrintNameThread pnt2 =
            new PrintNameThread("B");
        pnt2.start(); // Start the second thread
    }
}
Scheme 2: \texttt{start()} method is in a constructor of the subclass

1 class PrintNameThread \texttt{extends} Thread { 
2 \hspace{1em} PrintNameThread(String name) { 
3 \hspace{2em} super(name); 
4 \hspace{2em} \texttt{start>(); } //runs the thread once instantiated 
5 \hspace{1em} } 
6 \hspace{1em} public void \texttt{run()} { 
7 \hspace{2em} String name = \texttt{getName();} 
8 \hspace{2em} for (int i = 0; i < 100; i++) { 
9 \hspace{3em} System.out.print(name); 
10 \hspace{3em} } 
11 \hspace{1em} } 
12 \hspace{1em} } 
13 \hspace{1em} //continued
Scheme 2: Just creating an object instance starts a thread

14 class ExtendThreadClassTest2 {
15     public static void main(String args[]) {
16         PrintNameThread pnt1 =
17             new PrintNameThread("A");
18         PrintNameThread pnt2 =
19             new PrintNameThread("B");
20     }
21 }
22 }
Scheme 2: Just creating an object instance starts a thread

- Can modify `main` method as follows:

```java
14  class ExtendThreadClassTest3 {
15      public static void main(String args[]) {
16          new PrintNameThread("A");
17          new PrintNameThread("B");
18      }
19  }
```
Implementing Runnable Interface
Runnable Interface

• The *Runnable* interface should be implemented by any class whose instances are intended to be executed as a thread

• The class must define `run()` method of no arguments
  - The `run()` method is like `main()` for the new thread

• Provides the means for a class to be active while not subclassing *Thread*
  - A class that implements *Runnable* can run without subclassing *Thread* by instantiating a *Thread* instance and passing itself in as the target
Two Ways of Starting a Thread For a class that implements Runnable

1. Caller thread creates Thread object and starts it explicitly after an object instance of the class that implements Runnable interface is created
   - The start() method of the Thread object needs to be explicitly invoked after object instance is created

2. The Thread object is created and started within the constructor method of the class that implements Runnable interface
   - The caller thread just needs to create object instances of the Runnable class
Scheme 1: Caller thread creates a Thread object and starts it explicitly

// PrintNameRunnable implements Runnable interface
class PrintNameRunnable implements Runnable {

    String name;

    PrintNameRunnable(String name) {
        this.name = name;
    }

    // Implementation of the run() defined in the Runnable interface.
    public void run() {
        for (int i = 0; i < 10; i++) {
            System.out.print(name);
        }
    }

}
Scheme 1: Caller thread creates a Thread object and starts it explicitly

```java
public class RunnableThreadTest1 {

    public static void main(String args[]) {

        PrintNameRunnable pnt1 = new PrintNameRunnable("A");
        Thread t1 = new Thread(pnt1);
        t1.start();

    }
}
```
Scheme 2: Thread object is created and started within a constructor

// PrintNameRunnable implements Runnable interface
class PrintNameRunnable implements Runnable {

    Thread thread;

    PrintNameRunnable(String name) {
        thread = new Thread(this, name);
        thread.start();
    }

    // Implementation of the run() defined in the
    // Runnable interface.
    public void run() {
        String name = thread.getName();
        for (int i = 0; i < 10; i++) {
            System.out.print(name);
        }
    }
}
Scheme 2: Thread object is created and started within a constructor

public class RunnableThreadTest2 {

    public static void main(String args[]) {

        // Since the constructor of the PrintNameRunnable object creates a Thread object and starts it,  
        // there is no need to do it here. 
        new PrintNameRunnable("A");

        new PrintNameRunnable("B");
        new PrintNameRunnable("C");
    }
}
Extending Thread
Class vs.
Implementing
Runnable Interface
Extending Thread vs. Implementing Runnable Interface

- Choosing between these two is a matter of taste
- Implementing the `Runnable` interface
  - May take more work since we still
    - Declare a `Thread` object
    - Call the `Thread` methods on this object
  - Your class can still extend other class
- Extending the `Thread` class
  - Easier to implement
  - Your class can no longer extend any other class
ThreadGroup
ThreadGroup Class

• A thread group represents a set of threads
• In addition, a thread group can also include other thread groups
  – The thread groups form a tree in which every thread group except the initial thread group has a parent
• A thread is allowed to access information about its own thread group, but not to access information about its thread group's parent thread group or any other thread groups.
Example: ThreadGroup

```java
// Start three threads
new SimpleThread("Jamaica").start();
new SimpleThread("Fiji").start();
new SimpleThread("Bora Bora").start();

ThreadGroup group
    = Thread.currentThread().getThreadGroup();

Thread[] tarray = new Thread[10];
int actualSize = group.enumerate(tarray);
for (int i=0; i<actualSize;i++){
    System.out.println("Thread "+
tarray[i].getName() + " in thread group "
    + group.getName());
}
```
Synchronization
Race condition & How to Solve it

- Race conditions occur when multiple, asynchronously executing threads access the same object (called a shared resource) returning unexpected (wrong) results.
- Example:
  - Threads often need to share a common resource ie a file, with one thread reading from the file while another thread writes to the file.
- They can be avoided by synchronizing the threads which access the shared resource.
An Unsynchronized Example

```java
class TwoStrings {
    static void print(String str1, String str2) {
        System.out.print(str1);
        try {
            Thread.sleep(500);
        } catch (InterruptedException ie) {
        }
        System.out.println(str2);
    }

    //continued...
}
```
An Unsynchronized Example

class PrintStringsThread implements Runnable {
    Thread thread;
    String str1, str2;
    PrintStringsThread(String str1, String str2) {
        this.str1 = str1;
        this.str2 = str2;
        thread = new Thread(this);
        thread.start();
    }
    public void run() {
        TwoStrings.print(str1, str2);
    }
} //continued...
An Unsynchronized Example

class TestThread {
    public static void main(String args[]) {
        new PrintStringsThread("Hello ", "there.");
        new PrintStringsThread("How are ", "you?");
        new PrintStringsThread("Thank you ",
                                  "very much!");
    }
}
An Unsynchronized Example

- Sample output:
  Hello How are Thank you there.
  you?
  very much!
Synchronization: Locking an Object

- A thread is synchronized by becoming an owner of the object's monitor
  - Consider it as locking an object
- A thread becomes the owner of the object's monitor in one of three ways
  - Option 1: Use `synchronized` method
  - Option 2: Use `synchronized` statement on a common object
Option 1: Use synchronized method

```java
class TwoStrings {
    synchronized static void print(String str1, String str2) {
        System.out.print(str1);
        try {
            Thread.sleep(500);
        } catch (InterruptedException ie) {
        }
        System.out.println(str2);
    }
    //continued...
}
```
Option 1: Use synchronized method

class PrintStringsThread implements Runnable {
    Thread thread;
    String str1, str2;
    PrintStringsThread(String str1, String str2) {
        this.str1 = str1;
        this.str2 = str2;
        thread = new Thread(this);
        thread.start();
    }
    public void run() {
        TwoStrings.print(str1, str2);
    }
}
//continued...
Option 1: Use synchronized method

class TestThread {
    public static void main(String args[]) {
        new PrintStringsThread("Hello ", "there.");
        new PrintStringsThread("How are ", "you?");
        new PrintStringsThread("Thank you ",
                              "very much!");
    }
}
Option 1: Executing Synchronized Method

• Sample output:
  Hello there.
  How are you?
  Thank you very much!
Option 2: Use synchronized statement on a common object

```java
class TwoStrings {
    static void print(String str1, String str2) {
        System.out.print(str1);
        try {
            Thread.sleep(500);
        } catch (InterruptedException ie) {
        }
        System.out.println(str2);
    }
    //continued...
}
```
Option 2: Use synchronized statement on a common object

class PrintStringsThread implements Runnable {
    Thread thread;
    String str1, str2;
    TwoStrings ts;
    PrintStringsThread(String str1, String str2, TwoStrings ts) {
        this.str1 = str1;
        this.str2 = str2;
        this.ts = ts;
        thread = new Thread(this);
        thread.start();
    }
    //continued...
Option 2: Use synchronized statement on a common object

```java
public void run() {
    synchronized (ts) {
        ts.print(str1, str2);
    }
}

class TestThread {
    public static void main(String args[]) {
        TwoStrings ts = new TwoStrings();
        new PrintStringsThread("Hello ", "there.", ts);
        new PrintStringsThread("How are ", "you?", ts);
        new PrintStringsThread("Thank you ",
                                "very much!", ts);
    }
}
```
Inter-thread Synchronization
# Inter-thread Communication: Methods from Object Class

<table>
<thead>
<tr>
<th>Methods for Interthread Communication</th>
</tr>
</thead>
<tbody>
<tr>
<td>public final void wait()</td>
</tr>
<tr>
<td>Causes this thread to wait until some other thread calls the <code>notify</code> or <code>notifyAll</code> method on this object. May throw <code>InterruptedException</code>.</td>
</tr>
<tr>
<td>public final void notify()</td>
</tr>
<tr>
<td>Wakes up a thread that called the <code>wait</code> method on the same object.</td>
</tr>
<tr>
<td>public final void notifyAll()</td>
</tr>
<tr>
<td>Wakes up all threads that called the <code>wait</code> method on the same object.</td>
</tr>
</tbody>
</table>
wait() method of Object Class

- wait() method causes a thread to release the lock it is holding on an object; allowing another thread to run
- wait() method is defined in the Object class
- wait() can only be invoked from within synchronized code
- it should always be wrapped in a try block as it throws IOExceptions
- wait() can only invoked by the thread that owns the lock on the object
**wait() method of Object Class**

- When `wait()` is called, the thread becomes disabled for scheduling and lies dormant until one of four things occur:
  - another thread invokes the `notify()` method for this object and the scheduler arbitrarily chooses to run the thread
  - another thread invokes the `notifyAll()` method for this object
  - another thread interrupts this thread
  - the specified `wait()` time elapses

- When one of the above occurs, the thread becomes re-available to the Thread scheduler and competes for a lock on the object

- Once it regains the lock on the object, everything resumes as if no suspension had occurred
notify() method

- Wakes up a single thread that is waiting on this object's monitor
  - If any threads are waiting on this object, one of them is chosen to be awakened
  - The choice is arbitrary and occurs at the discretion of the implementation
- Can only be used within synchronized code
- The awakened thread will not be able to proceed until the current thread relinquishes the lock on this object
Inter-thread Communication: Producer-Consumer Example
Inter-thread Communication

Customer
- comes in
  - notifies the waiter
- chooses order
  - asks the waiter to wait
- gives order
  - notifies the waiter

Waiter (waiting)
- goes to the customer
- waits for the order
- takes the order

Customer
- waits for the order
- asks the customer to wait
- leaves the restaurant

Waiter
- eats the food
- notifies the customer
- returns with the food
- waits again
Imagine a scenario in which there exists two distinct threads both operating on a single shared data area.

One thread, the Producer inserts information into the data area whilst the other thread, the Consumer, removes information from that same area.

In order for the Producer to insert information into the data area, there must be enough space.

- The Producer's sole function is to insert data into the data-area, it is not allowed to remove any data from the area.
Producer-Consumer

• For the Consumer to be able to remove information from the data area, there must be information there in the first place
  – The sole function of the Consumer is to remove data from the data area

• The solution of the Producer-Consumer problem lies with devising a suitable communication protocol through which the two processes may exchange information.

• The definition of such a protocol is the main factor that makes the Producer-Consumer problem interesting in terms of concurrent systems
Unsynchronized Producer-Consumer Example: CubbyHole.java

```java
public class CubbyHole {
    private int contents;

    public int get() {
        return contents;
    }

    public synchronized void put(int value) {
        contents = value;
    }
}
```
public class Producer extends Thread {
    private CubbyHole cubbyhole;
    private int number;

    public Producer(CubbyHole c, int number) {
        cubbyhole = c;
        this.number = number;
    }

    public void run() {
        for (int i = 0; i < 10; i++) {
            cubbyhole.put(i);
            System.out.println("Producer "+ " put: "+ i);
            try {
                sleep((int)(Math.random() * 100));
            } catch (InterruptedException e) { }
        }
    }
}
public class Consumer extends Thread {
    private CubbyHole cubbyhole;
    private int number;

    public Consumer(CubbyHole c, int number) {
        cubbyhole = c;
        this.number = number;
    }

    public void run() {
        int value = 0;
        for (int i = 0; i < 10; i++) {
            value = cubbyhole.get();
            System.out.println("Consumer #" + this.number + " got: " + value);
        }
    }
}
public class ProducerConsumerUnsynchronized {

    public static void main(String[] args) {

        CubbyHole c = new CubbyHole();

        Producer p1 = new Producer(c, 1);
        Consumer c1 = new Consumer(c, 1);

        p1.start();
        c1.start();
    }
}
Result of Unsynchronized Producer-Consumer

• Results are unpredictable
  – A number may be read before a number has been produced
  – Multiple numbers may be produced with only one or two being read
Result of Unsynchronized Producer-Consumer

Consumer #1 got: 0
Producer #1 put: 0
Consumer #1 got: 0
Consumer #1 got: 0
Consumer #1 got: 0
Consumer #1 got: 0
Consumer #1 got: 0
Consumer #1 got: 0
Consumer #1 got: 0
Consumer #1 got: 0
Producer #1 put: 1
Producer #1 put: 2
Producer #1 put: 3
Producer #1 put: 4
Producer #1 put: 5
Producer #1 put: 6
Producer #1 put: 7
Producer #1 put: 8
Producer #1 put: 9
public class CubbyHole {
    private int contents;
    private boolean available = false;

    public synchronized int get() {
        while (available == false) {
            try {
                wait();
            } catch (InterruptedException e) { }
        }
        available = false;
        notifyAll();
        return contents;
    }
    // continued
}
public synchronized void put(int value) {
    while (available == true) {
        try {
            wait();
        } catch (InterruptedException e) { }
    }
    contents = value;
    available = true;
    notifyAll();
}
Result of Synchronized Producer-Consumer

Producer 1 put: 0
Consumer 1 got: 0
Producer 1 put: 1
Consumer 1 got: 1
Producer 1 put: 2
Consumer 1 got: 2
Producer 1 put: 3
Consumer 1 got: 3
Producer 1 put: 4
Consumer 1 got: 4
Producer 1 put: 5
Consumer 1 got: 5
Producer 1 put: 6
Consumer 1 got: 6
Producer 1 put: 7
Consumer 1 got: 7
Producer 1 put: 8
Consumer 1 got: 8
Producer 1 put: 9
Consumer 1 got: 9
Scheduling a task via Timer & TimerTask Classes
Timer Class

- Provides a facility for threads to schedule tasks for future execution in a background thread
- Tasks may be scheduled for one-time execution, or for repeated execution at regular intervals.
- Corresponding to each Timer object is a single background thread that is used to execute all of the timer's tasks, sequentially
- Timer tasks should complete quickly
  - If a timer task takes excessive time to complete, it "hogs" the timer's task execution thread. This can, in turn, delay the execution of subsequent tasks, which may "bunch up" and execute in rapid succession when (and if) the offending task finally completes.
TimerTask Class

- Abstract class with an abstract method called run()
- Concrete class must implement the run() abstract method
Example: Timer Class

public class TimerReminder {

    Timer timer;

    public TimerReminder(int seconds) {
        timer = new Timer();
        timer.schedule(new RemindTask(), seconds*1000);
    }

    class RemindTask extends TimerTask {
        public void run() {
            System.out.format("Time's up!\n");
            timer.cancel(); //Terminate the timer thread
        }
    }

    public static void main(String args[]) {
        System.out.format("About to schedule task.\n");
        new TimerReminder(5);
        System.out.format("Task scheduled.\n");
    }
}
